## WHAT IS CLAIMED IS:

A video signal processor comprising:

a first motion detection unit for finding a difference between a luminance signal included in a predetermined composite video signal in a current frame and a luminance signal included in a composite video signal in a past frame having a predetermined time interval and outputting a first motion detection signal in accordance with the difference:

luminance signals included in a plurality of composite video signals in said current frame based on a plurality of composite video signals having a predetermined interval in a vertical direction in said current frame and a plurality of predetermined composite video signals in the vertical direction at the same position in said past frame, detecting the correlation of color signal components remaining in the extracted video signals, and outputting a second motion detection signal in accordance with the result of the detection;

a color signal difference calculating means for calculating a difference of absolute values of color signals in the current frame calculated based on said

three composite video signals in said current frame and color signals in the past frame calculated based on the composite video signals of said past frame;

a selecting means for selecting the difference of said color signals calculated by said color 5 signal difference calculating means when either of said first motion detection signal or said second motion detection signal indicates that there is motion and selecting an intended value indicating that there is no 10 motion when both of said first motion detection signal and said second motion detection signal indicate that there is no motion; and

a motion coefficient generating means for outputting a motion coefficient indicating motion in accordance with the value selected by said selecting means.

- 2. A video signal processor as set forth in claim 1, wherein said second motion detection unit comprises:
- 20 a first horizontal correlation detection unit for outputting a first horizontal correlation detection signal in accordance with a difference between said extracted luminance signal and a delay signal obtained by

20

delaying the luminance signal by exactly one period's worth of said color sub-carrier wave,

a second horizontal correlation detection
unit for outputting a second horizontal correlation
detection signal in accordance with an amplitude of the
signal obtained by passing said extracted luminance
signal through a band pass filter using the frequency of
said color sub-carrier wave as the center frequency, and

a logical circuit for generating a horizontal correlation detection signal indicating the horizontal correlation of color signals in accordance with a logical AND of said first and second horizontal correlation detection signals.

- 3. A video signal processor as set forth in
  15 claim 2, wherein said second motion detection unit
  comprises:
  - a first vertical correlation detection unit for outputting a first vertical correlation detection signal in accordance with a difference between first and third luminance signals extracted from the composite video signals in which corresponding color signals have the same phase in accordance with first, second, and third luminance signals extracted from three composite

15

video signals in the vertical direction in said current frame,

a second vertical correlation detection unit for outputting a second vertical correlation detection signal in accordance with a difference between signals obtained from the first and the second luminance signals corresponding to the composite video signals in which corresponding color signals have inverse phases passed through the band pass filter using the frequency of the color sub-carrier wave as the center frequency,

a third vertical correlation detection unit for outputting a third vertical correlation detection signal in accordance with a difference of signals obtained from the second and third luminance signals corresponding to the composite video signals in which corresponding color signals have inverse phases passed through the band pass filter using the frequency of the color sub-carrier wave as the center frequency,

a logical circuit for generating a vertical correlation detection signal indicating vertical correlation of the color signals in accordance with the logical AND of said first, second, and third vertical correlation detection signals, and

10

15

20

a logical operation circuit for outputting said second motion detection signal in accordance with the logical AND of said horizontal correlation detection signal and said vertical correlation detection signal.

4. A video signal processor comprising:

a first motion detection unit for finding a difference between a luminance signal included in a predetermined composite video signal in a current frame and a luminance signal included in a composite video signal in a past frame having a predetermined time interval and outputting a first motion detection signal in accordance with the difference;

luminance signals included in three composite video signals in said current frame based on three composite video signals having a predetermined interval in a vertical direction in said current frame and three predetermined composite video signals in the vertical direction at the same position in said past frame, detecting the correlation of color signal components remaining in the extracted video signals, and outputting a second motion detection signal in accordance with the result of the detection;

SON-2974 (80001-2974) Application No.: 10/809,516

10

20

a color signal difference calculating means for calculating a difference of absolute values of color signals in the current frame calculated based on said three composite video signals in said current frame and color signals in the past frame calculated based on the composite video signals of said past frame;

a first selecting means for selecting the difference of said color signals calculated by said color signal difference calculating means when said first motion detection signal indicates that there is motion and selecting an intended first value indicating that there is no motion when said first motion detection signal indicates that there is no motion;

a second selecting means for selecting an

intended second value indicating that there is motion

when said second motion detection signal indicates that

there is motion and selecting the output signal of said

first selecting means when said second motion detection

signal indicates that there is no motion; and

a motion coefficient generating means for outputting the motion coefficient indicating motion in accordance with the value selected by said second selecting means.

- 5. A video signal processor as set forth in claim 4, wherein said second motion detection unit comprises:
- a first horizontal correlation detection unit
  for outputting a first horizontal correlation detection
  signal in accordance with a difference between said
  extracted luminance signal and a delay signal obtained by
  delaying the luminance signal by exactly one period's
  worth of said color sub-carrier wave.
- a second horizontal correlation detection
  unit for outputting a second horizontal correlation
  detection signal in accordance with an amplitude of the
  signal obtained by passing said extracted luminance
  signal through a band pass filter using the frequency of
  said color sub-carrier wave as the center frequency, and
  - a logical circuit for generating a horizontal correlation detection signal indicating the horizontal correlation of color signals in accordance with a logical AND of said first and second horizontal correlation detection signals.
  - 6. A video signal processor as set forth in claim 5, wherein said second motion detection unit comprises:

15

20

a first vertical correlation detection unit for outputting a first vertical correlation detection signal in accordance with a difference between first and third luminance signals extracted from the composite video signals in which corresponding color signals have the same phase in accordance with first, second, and third luminance signals extracted from three composite video signals in the vertical direction in said current frame,

a second vertical correlation detection unit for outputting a second vertical correlation detection signal in accordance with a difference between signals obtained from the first and the second luminance signals corresponding to the composite video signals in which corresponding color signals have inverse phases passed through the band pass filter using the frequency of the color sub-carrier wave as the center frequency,

a third vertical correlation detection unit
for outputting a third vertical correlation detection
signal in accordance with a difference of signals
obtained from the second and third luminance signals
corresponding to the composite video signals in which
corresponding color signals have inverse phases passed

SON-2974 (80001-2974) 76 CLEAN VERSION OF Application No.: 10/809,516 SUBSTITUTE SPECIFICATION

through the band pass filter using the frequency of the color sub-carrier wave as the center frequency,

a logical circuit for generating a vertical correlation detection signal indicating vertical correlation of the color signals in accordance with the logical AND of said first, second, and third vertical correlation detection signals, and

a logical operation circuit for outputting said second motion detection signal in accordance with the logical AND of said horizontal correlation detection signal and said vertical correlation detection signal.

- 7. A TV receiver for judging motion of an image in accordance with a motion coefficient generated based on a composite video signal, separating a luminance signal and a color signal from said composite video signal by using a frame comb filter for a still image having no motion, separating a luminance signal and a color signal from said composite video signal by using a band pass filter or a two-dimensional comb filter for a moving picture having motion and reproducing a video signal, comprising:
- a first motion detection unit for finding a difference between a luminance signal included in a

15

20

predetermined composite video signal in a current frame and a luminance signal included in a composite video signal in a past frame having a predetermined time interval and outputting a first motion detection signal in accordance with the difference;

luminance signals included in three composite video signals in said current frame based on three composite video signals having a predetermined interval in a vertical direction in said current frame and three predetermined composite video signals in the vertical direction at the same position in said past frame, detecting the correlation of color signal components remaining in the extracted video signals, and outputting a second motion detection signal in accordance with the result of the detection;

a color signal difference calculating means for calculating a difference of absolute values of color signals in the current frame calculated based on said three composite video signals in said current frame and color signals in the past frame calculated based on the composite video signals of said past frame;

a selecting means for selecting the

20

difference of said color signals calculated by said color signal difference calculating means when either of said first motion detection signal or said second motion detection signal indicates that there is motion and selecting an intended value indicating that there is no motion when both of said first motion detection signal and said second motion detection signal indicate that there is no motion; and

a motion coefficient generating means for outputting a motion coefficient indicating motion in accordance with the value selected by said selecting means.

- 8. A TV receiver for judging motion of an image in accordance with a motion coefficient generated based on a composite video signal, separating a luminance signal and a color signal from said composite video signal by using a frame comb filter for a still image having no motion, separating a luminance signal and a color signal from said composite video signal by using a band pass filter or a two-dimension comb filter for a moving picture having motion and reproducing the video signal, comprising:
  - a first motion detection unit for finding a

15

20

difference between a luminance signal included in a predetermined composite video signal in a current frame and a luminance signal included in a composite video signal in a past frame having a predetermined time interval and outputting a first motion detection signal in accordance with the difference;

a second motion detection unit for extracting luminance signals included in a plurality of composite video signals in said current frame based on a plurality of composite video signals having a predetermined interval in a vertical direction in said current frame and a plurality of predetermined composite video signals in the vertical direction at the same position in said past frame, detecting the correlation of color signal components remaining in the extracted video signals, and outputting a second motion detection signal in accordance with the result of the detection;

a color signal difference calculating means for calculating a difference of absolute values of color signals in the current frame calculated based on said three composite video signals in said current frame and color signals in the past frame calculated based on the composite video signals of said past frame;

a first selecting means for selecting the difference of said color signals calculated by said color signal difference calculating means when said first motion detection signal indicates that there is motion and selecting an intended first value indicating that there is no motion when said first motion detection signal indicates that there is no motion;

a second selecting means for selecting an intended second value indicating that there is motion when said second motion detection signal indicates that there is motion and selecting the output signal of said first selecting means when said second motion detection signal indicates that there is no motion; and

a motion coefficient generating means for

15 outputting a motion coefficient indicating motion in

accordance with the value selected by said second

selecting means.
